

Suitability Analysis for Athens, GA Training Center

This raster model of suitability shows continuous areas that are suitable for development, whereas the vector model only showed individual parcels that were suitable for development. In the vector model, if the entire parcel (or at least most of the parcel) isn't suitable according to our requirements then the parcel wasn't indicated as suitable. With the raster model, we can see the continuous areas that are suitable, even if they aren't representative of a parcel. This could enable developers to see the entire area that is best for development, including the area across different parcels, and how many total parcels they would need to buy to have access to the entire area.
